23 systems;  
24 Tree-based

**Abstract** Matsuzaki et al. had proposed a flexible tree-based key management 25  
framework for a terminal to connect with multiple content distribution systems 26  
(CDSs) using a public bulletin board. In their scheme, the key management center 27  
constructs the public bulletin board by utilizing symmetric cryptosystem to protect 28  
terminal node keys. On the other hand, the terminals can obtain its node keys by 29  
decrypting the cipher which is posted on the public bulletin board of CDS. However, 30  
this method is not efficient for a large group which has a number of terminals. When 31  
a terminal changes its membership, the key managerial center needs a large 32  
amount of computation to structure the public bulletin, and the terminal cannot 33  
efficiently compute its node keys from the large public bulletin board. In this paper, 34  
we propose an improved scheme to structure a public bulletin board efficiently by 35  
the key management center of CDS. The improved scheme is capable of a large 36  
group of terminals and ensures that low powered equipment can efficiently obtain 37  
their node key. 38

## 40 Introduction

41 In a new service environment, home users in-  
42 creasingly use CATV cables, radio broadcasts, and  
43 the Internet to digitally access, store, and play  
44 music, movies, or other kinds of entertainment in  
45 their lives. Recently, the most widely used tech-  
46 nique is transferring digital data over the Internet,  
47 such as Web TV or Web movies. The providers offer  
48 high-value digital content, such as software or  
49 multimedia data distributes contents, in a public  
50 channel, and prior payment for the content cannot  
51 be bypassed. One of the basic ideas is distributing  
52 the encrypted digital content through an insecure  
53 channel. For the purpose of distributing security  
54 and performance improvement, the authorized  
55 members of a group can share a symmetric group  
56 key so that they can decrypt the group communi-  
57 cation content.

58 In a realistic world, one of useful applications is  
59 the network conferences of a company. Every  
60 conference has its exclusive conference key to  
61 protect the communicative contents in the enter-  
62 prise network. For example, every team member  
63 has his private key for obtaining the team confer-  
64 ence key. He uses the team conference key to  
65 decrypt the contents of the communication and to  
66 encrypt the information he wants to share during  
67 the conference. A person who does not belong to  
68 this team cannot join the conference because he  
69 does not have the correct conference key to  
70 encrypt or decrypt the information. Another useful  
71 application is to protect the documents of a com-  
72 pany. The documents can be encrypted with  
73 a company secret key and put on a public network  
74 for employees' use. Every employee has his private  
75 key for obtaining the company secret key, and the  
76 employee can securely retrieve the documents of  
77 his company anywhere. Therefore, if there is an  
78 efficient key management mechanism, the mech-  
79 anism could be widely applied.

80 Several approaches with the tree-based key  
81 management have been proposed (Chang et al.,  
82 1992; Hwang 1999a; Lin et al., 2003; Shen and  
83 Chen, 2002). The logical key hierarchy was pro-  
84 posed by Wong et al. (2000) and the binary key  
85 tree management was proposed by Wallner et al.  
86 (1998) to reduce complexity of key management of  
87 a group. For a large group with frequent member-  
88 ship changed, the cost of re-keying the group is  
89 raised. Therefore, some reducible cost schemes  
90 had been proposed for achieving the best possible  
91 performance (Banerjee and Bhattacharjee, 2002;  
92 Chang et al., 1999; Chen and Chung, 2002; Chien  
93 and Jan, 2003; Hwang, 1999b; Lin et al., 2004;

Snoeyink et al., 2001; Waldvogel et al., 1999; 94  
Zhong, 2002). In most cases, they only focus on 95  
the scheme which has a fixed management center 96  
in CDS. Matsuzaki et al. (2003) proposed a scheme 97  
to construct a key management framework by 98  
combining various key management schemes of 99  
CDS. A terminal which plays a home server can 100  
connect with multiple CDSs. By the public bulletin 101  
board, the terminal can compute its root key that 102  
is used to decrypt an encrypted digital content. 103  
However, the above schemes are not efficient in 104  
structuring the public board, and also not suitable 105  
for low powered equipment to obtain node keys. 106

107 In this paper, we propose an improved method  
108 to match the requirement of low powered equip-  
109 ment. The improved scheme can efficiently con-  
110 struct the public bulletin board and the terminal  
111 also can efficiently compute its node keys. Fur-  
112 thermore, our scheme has less calculating oper-  
113 ations than Matsuzaki's in the framework.

114 The remainder of this paper is organized as  
115 follows. In next section, we briefly review the public  
116 bulletin board in framework and show why Matsu-  
117 zaki et al.'s scheme is not efficient enough. Then,  
118 the improved scheme is presented. Further, we  
119 analyze the security and efficiency of our scheme.  
120 Finally, we have our conclusion in last section.

## Review of Matsuzaki et al.'s framework 121

122 In this section, there are two mechanisms in the  
123 CDS<sub>c</sub>. One is KMA (Key Management Authority)  
124 which generates  $UK_i^c = H(CK_i || c)$  for terminal  $i$   
125 where  $c$  is an identity of the CDS<sub>c</sub>,  $CK_i$  is the  
126 secret key of terminal  $i$  and  $H(\cdot)$  is a secure one-  
127 way function. The other mechanism is KMC (Key  
128 Management Center) which determines the tree  
129 structure and calculates all node keys on the  
130 public bulletin board. Initially, KMA computes all  
131  $UK_i^c$  and transmits them to KMC in a secure  
132 channel. The KMC uses the all  $UK_i^c$  to structure  
133 the public bulletin board, and later every termi-  
134 nal can obtain its node keys from the board. The  
135 following are steps for KMC building the public  
136 bulletin board.

Step 1. Determine the inner node keys  $K_j^c$  accord-  
ing to the tree structure in Fig. 1, where  $j$   
is an inner node number.

$$\text{Layer 0: } K_0^c = H(K_1^c),$$

$$\text{Layer 1: } K_1^c = H(K_3^c), K_2^c = H(K_5^c),$$

$$\text{Layer 2: } K_3^c = H(UK_0^c), K_4^c = H(UK_2^c),$$

$$K_5^c = H(UK_4^c), K_6^c = H(UK_6^c).$$

Figure 1 An example of a complete binary tree.

Step 2. Use the  $K_j^c$  to generate and publish the encrypted messages on the public bulletin board as follows:

Layer 0:  $E(K_0^c, K_0^c)$ ,  
 Layer 1:  $E(K_4^c, K_1^c)$ ,  $E(K_6^c, K_2^c)$ ,  
 Layer 2:  $E(UK_1^c, K_3^c)$ ,  $E(UK_3^c, K_4^c)$ ,  
 $E(UK_5^c, K_5^c)$ ,  $E(UK_7^c, K_6^c)$ .

151 The terminal  $i$  calculates its inner node key from  
 152 the information of the public bulletin board ac-  
 153 cording to its location on the complete binary tree.  
 154 If the terminal  $i$  is a left child of its upper inner  
 155 node, the terminal  $i$  computes  $H(\cdot)$  function to  
 156 obtain the upper inner node key  $K_j^c$ . Otherwise, the  
 157 terminal  $i$  decrypts the cipher which is posted on  
 158 the public bulletin board to obtain the key  $K_j^c$ .  
 159 From this located leaf node to the upper layer  
 160 inner nodes, the terminal  $i$  uses the same method  
 161 until it obtains its root node key  $K_0^c$ .

162 For a large group of the CDS, most of the right  
 163 terminals must spend more computing time to  
 164 calculate the root key. Because of continuous  
 165 decrypting the cipher in a high depth tree struc-  
 166 ture, the most right terminals cannot efficiently  
 167 get the root key. Especially, the electric applian-  
 168 ces which have a low computation ability will  
 169 spend more time to obtain the root key. In order  
 170 to access the node keys quickly, we improved  
 171 Matsuzaki et al.'s scheme to suit low computing  
 172 equipment.

## 173 The proposed scheme

174 In this section, we propose an improved method to  
 175 structure the public bulletin board. Our scheme of  
 176 the public bulletin board is also composed of three  
 177 stages: initiative stage, structuring public bulletin  
 178 board stage and obtaining keys stage.

179 In the initiative stage, the scheme and notations  
 180  $\{i, CK_i, c, UK_i, j, H(\cdot)\}$  are the same as those in  
 181 Matsuzaki et al.'s scheme. In structuring the public

bulletin board stage, we utilize XOR( $S, S'$ ) function  
 that computes data  $S$  and  $S'$  in order to conceal  
 secret information. Our proposal consists of the  
 following steps:

Step 1: Determine the inner node keys  $K_j^c$  accord-  
 ing to the tree structure in Fig. 1.

Layer 0:  $K_0^c = H(K_1^c)$ ,

Layer 1:  $K_1^c = H(K_3^c)$  and  $K_2^c = H(K_5^c)$ ,

Layer 2:  $K_3^c = H(UK_0^c)$ ,  $K_4^c = H(UK_2^c)$ ,  
 $K_5^c = H(UK_4^c)$ , and  $K_6^c = H(UK_6^c)$ .

Step 2: Use the  $K_j^c$  and XOR operation to generate  
 and publish the information on the public  
 bulletin board.

Layer 0: XOR( $K_0^c, H(K_0^c)$ ),

Layer 1: XOR( $K_1^c, H(K_4^c)$ ) and  
 XOR( $K_2^c, H(K_6^c)$ ),

Layer 2: XOR( $K_3^c, H(UK_1^c)$ ), XOR( $K_4^c, H(UK_3^c)$ ),  
 XOR( $K_5^c, H(UK_5^c)$ ), and XOR( $K_6^c, H(UK_7^c)$ ).

In obtaining the keys stage, a terminal  $i$  calcu-  
 lates its inner node keys according to its location in  
 the tree. Hence, a terminal  $i$  must know its location  
 of leaves in the tree. The terminal  $i$  can question its  
 related information from the public bulletin board.  
 If the terminal  $i$  is the left leaf of its upper inner  
 node keys, the terminal  $i$  computes  $H(\cdot)$  to obtain  
 the upper node key  $K_j^c$ . Otherwise, the terminal  $i$  is  
 the right leaf of its upper inner node so it calculates  
 XOR operation to get the upper node key  $K_j^c$ . Until  
 having the root node key, the terminal  $i$  executes  
 $H(\cdot)$  or XOR operation which depends on its location  
 on left or right side of the upper inner node. For  
 example, terminal 3 has the leaf key  $UK_3^c$  in  $CDS_c$ ,  
 so it obtains upper  $K_4^c$  by computing  
 XOR( $H(UK_3^c), XOR(H(K_4^c), XOR(H(UK_5^c)))$ ).

Next, terminal 3 obtains  $K_1^c$  by computing  
 XOR( $H(K_4^c), XOR(K_1^c, H(K_4^c))$ ) because its location is  
 in the right child of the position of inner node key  
 $K_1^c$  in this moment. Finally, terminal 3 obtains  $K_0^c$  by  
 computing  $H(K_1^c)$  because it is the left child of the  
 inner node key  $K_0^c$ . Terminal 3 can obtain  $K_4^c$ ,  $K_1^c$ ,  
 and  $K_0^c$  from its leaf to root node  $i$  according to the  
 following pseudo code:

```
node_key = UKi
WHILE node_key < > root_node_key
IF Position in Parent.RightChild THEN
    node_key = XOR(node_key, Position.
    CipherInformation)
ELSE
    Node_key = H(node_key)
END WHILE
```

## 226 Efficiency and security analysis

227 In this section, the efficiency and security of the  
228 proposed method are analyzed. Matsuzaki et al.'s  
229 scheme uses encryption algorithm to obscure the  
230 information of inner node keys in order to reach  
231 the security requirement. In generalization, an  
232 encrypted method must possess a complex algo-  
233 rithm to obscure a plaintext message, such as DES  
234 (Data Encryption Standard) cryptosystem which  
235 includes steps of the initial permutation, the key  
236 transformation, the expansion permutation, the  
237 S-Box substitution, the P-Box permutation and the  
238 final permutation in [Menezes et al. \(1996\)](#). Our  
239 scheme uses the XOR operator to replace the  
240 encrypted cryptosystem, because it is more  
241 efficient.

242 Compared with Matsuzaki et al.'s scheme, the  
243 number of computing times of the most right  
244 terminal  $i$  to obtain the root key depends on the  
245 depth  $l$  of the complete binary tree. In our scheme,  
246 terminal  $i$  can efficiently compute  $l \times \text{XOR}(S, S')$   
247 for the root key. On the other hand, Matsuzaki  
248 et al.'s scheme must compute  $l \times E(K, M)$  for the  
249 root key. We have performed an experiment by  
250 using a PC (2.0 GHz Pentium-4 CPU with 512 MB  
251 RAM) to test the software performance. The simu-  
252 lation is performed with a simulator using Java  
253 language in the UNIX operating system. In [Table 1](#),  
254 our scheme uses the XOR operation and Matsuzaki  
255 et al.'s scheme uses a DES cryptosystem for  
256 computing the root key at a depth of 5000,  
257 10 000, and 20 000 layers of a complete binary tree.  
258 Evidently, our scheme has a higher performance.

259 Next is the security analysis for our scheme. The  
260 possible attacks for breaking our scheme is an  
261 adversary from an internal or external environ-  
262 ment. In the remainder of this section, several  
263 attacks will be raised and we demonstrate how to  
264 fight against these attacks.

265 *Attack 1:* A non-attending terminal  $e \notin \text{CDS}_c$   
266 tries to obtain the root key  $K_0^c$  from the public  
267 bulletin board.

268 *Analysis of Attack 1:* A non-attending terminal  
269  $e \notin \text{CDS}_c$  must have one of  $\{\text{UK}_0^c, \dots, \text{UK}_i^c\}$  to com-  
270 pute the inner node key. However, to form the

valid value  $\text{UK}_c^i = H(\text{CK}_i \parallel c)$  needs a secret key  $\text{CK}_i$  271  
which was securely transferred from the KMA. 272  
Hence, if any non-attending terminal  $e$  wants to 273  
get the root node key, it must inverse the one-way 274  
function. Basically, it is hard to derive  $x$  from the 275  
 $H(x)$  and also difficult to find another message  $x'$  276  
satisfying  $H(x) = H(x')$ . For this reason, it is im- 277  
possible for any outside adversary to reveal the 278  
inner node key. 279

*Attack 2:* An attending terminal  $y \in \text{CDS}_c$  tries to 280  
obtain the brother terminal  $z$ 's  $\text{CK}_z$  from the public 281  
bulletin board for free use of digital content. 282

*Analysis of Attack 2:* If an attending terminal 283  
 $y \in \text{CDS}_c$  tries to steal the brother terminal  $z$ 's  $\text{CK}_z^c$  284  
for getting free digit content, it equally faces 285  
solving a one-way function question as we men- 286  
tioned in [Attack 1](#). Hence, terminal  $y$  cannot forge 287  
the valid  $\text{UK}_z^c$  without knowing  $\text{CK}_z^c$ . 288

*Attack 3:* A terminal  $y \in \text{CDS}_c$  should not obtain 289  
the node keys only if it uses the associated 290  
terminal leaf along the path to its root. 291

*Analysis of Attack 3:* A terminal  $y \in \text{CDS}_c$  effi- 292  
ciently obtains the node keys from its associated 293  
terminal leaf along the path to the root. If 294  
terminal  $y$  wants to obtain the other node keys, 295  
to calculate the inversion of a one-way function is 296  
difficult. Hence, terminal  $y$  cannot efficiently get 297  
the other node keys and use the node key to forge 298  
the illegitimate information. 299

## Conclusions

300

We have proposed an improved flexible tree-based 301  
key management framework. When a terminal 302  
connects to the designated CDS, the terminal can 303  
efficiently compute its inner node keys from 304  
a public bulletin board, and it does not need to 305  
have a high computing ability. In other words, it 306  
could be used in mostly low powered equipment, 307  
such as being used in a wireless environment. 308  
Simultaneously, the management center of CDS 309  
can also efficiently structure a public bulletin 310  
board with less computation. Moreover, our 311  
scheme is secure against the adversary attacks 312  
from the external and internal system. 313

- 369 **Min-Shiang Hwang** was born on August 27, 1960 in Tainan,  
370 Taiwan, Republic of China (ROC). He received the B.S. in  
371 Electronic Engineering from National Taipei Institute of  
Technology, Taipei, Taiwan, ROC, in 1980; the M.S. in Industrial  
Engineering from National Tsing Hua University, Taiwan, in  
1988; and the Ph.D. in Computer and Information Science from  
National Chiao Tung University, Taiwan, in 1995. He also studied  
Applied Mathematics at National Cheng Kung University,  
Taiwan, from 1984 to 1986. Dr. Hwang passed the National  
Higher Examination in field "Electronic Engineer" in 1988. He  
also passed the National Telecommunication Special Examina-  
tion in field "Information Engineering", qualified as advanced  
technician in the first class in 1990. From 1988 to 1991, he was  
the leader of the Computer Center at Telecommunication  
Laboratories (TL), Ministry of Transportation and Communica-  
tions, ROC. He was also a chairman of the Department of  
Information Management, Chaoyang University of Technology  
(CYUT), Taiwan, during 1999–2002. He was a professor and  
chairman of the Graduate Institute of Networking and Commu-  
nications, CYUT, during 2002–2003. He obtained the 1997,  
1998, 1999, 2000, and 2001 Distinguished Research Awards of  
the National Science Council of the Republic of China. He is  
currently a professor of the Department of Management  
Information System, National Chung Hsing University, Taiwan,  
ROC. He is a member of IEEE, ACM, and Chinese Information  
Security Association. His current research interests include  
electronic commerce, database and data security, cryptogra-  
phy, image compression, and mobile computing. Dr. Hwang has  
published 100 articles on the above research fields in inter-  
national journals.
- Jung-Wen Lo** was born on February 21, 1964 in Taiwan. He  
received the B.S. degree in Information and Computer  
Engineering in 1987 from Chung Yuan Christian University,  
Chung-Li, Taiwan and the M.S. degree in Computer Science &  
Information Systems in 1994 from Texas A& M University at  
Commerce, Texas, USA. He is working for his Ph.D. program in  
the Department of Computer Science at National Chung Hsing  
University, Taichung, Taiwan. He was an Associate Engineer in  
Product Development Department of Institute for Information  
Industry from 1994 to 1996. Since August 1998, he has been an  
Instructor of the Department of Information Management at  
National Taichung Institute of Technology, Taichung, Taiwan.  
His research interests include electronic commerce, computer  
cryptography and computer networks.
- Chia-Hsin Liu** was born in Miao-Li, Taiwan, Republic of China,  
on August 1, 1979. He received the B.S. and M.S. degrees in  
Department of Information Management and Graduate Institute  
of Networking and Communication Engineering from Chaoyang  
University of Technology, Taichung, Taiwan, in 2002 and 2004,  
respectively. He is currently a System Engineer in OmniWise  
International Inc. His research interests include  
cryptography, information security, database security and  
network security.
